Nicolás Roser Nebot
University of Malaga, Spain

Abstract—With the arrival of Muslims in 711 till their expulsion in the 1600s, Arabic language was present in Spain for more than eight centuries. Although social networks have become a valuable resource for mining sentiments, there is no previous research investigating the layman’s sentiment towards Spanish words of Arabic etymology related to Islamic terminology. This study aim at analyzing Spanish words of Arabic origin related to Islam. A random sample of 4586 out of 45860 tweets was used to evaluate general sentiment towards some Spanish words of Arabic origin related to Islam. An expert-predefined Spanish lexicon of around 6800 seed adjectives was used to conduct the analysis. Results indicate a generally positive sentiment towards several Spanish words of Arabic etymology related to Islam. By implementing both a qualitative and quantitative methodology to analyze tweets’ sentiments towards Spanish words of Arabic etymology, this research adds breadth and depth to the debate over Arabic linguistic influence on Spanish vocabulary.

Index Terms—Spanish words of Arabic origin, sentiment analysis, Text mining, Twitter

I. INTRODUCTION

In 711 a contingent of Muslims led by Tariq Ibn Ziyad crossed North Africa via Gibraltar to the Iberian peninsula. In a few years, Muslims ruled nearly all Iberia or modern day Spain and Portugal. Muslims stayed in Iberia from 711 till their expulsion in 1600s. Over more than eight centuries, Arabic became the language of culture and administration (Plann, 2009). Some authors argue that the greatest Arabic influence of Arabic on Spanish language is lexical, where around 8% of Spanish vocabulary may be traced to Arabic origin (Quintana & Mora, 2002). This includes probably thousands of modern geographic locations that still hold Arabic toponyms dating back to the Moors. Figure 1 shows only 17 of such toponyms in Spain. In fact, it is quite common to find places that contain the word “Guada-”, meaning “river/valley” in Arabic. Examples include “Guadalajara” or “wadi al-hijarah/valley of stones”, “Guadalaviar” or “wadi al-abyad/white valley” and “Guadalcazar” or “wadi al-qasr/valley of castle.” (Please refer to Appendix for more details).
Social media users represent are estimated to represent around 67 percent of the billion Internet active users (Eirinaki, Pisal & Singh, 2012). Thus, social networks play a major role in shaping public opinion’s attitudes in areas as diverse as voting, buying products and stock markets prediction (Bai, 2011; Eirinaki, Pisal & Singh, 2012). Kim and Hovy (2004) define an opinion “as a statement in which the opinion holder makes a specific claim about a topic using a certain sentiment.”. Online opinions expressed in social networks have been exploited in mining individuals’ sentiments through text filtering and mining (Zhang, Zeng, Li, Wang & Zuo, 2009). Social networks’ opinions are generally analyzed through natural language processing (NLP) sentiment analysis techniques. Sentiment analysis is also known as opinion mining, review mining, emotional polarity analysis (EPA), or appraisal extraction (Zagal, Tomuro & Shepitsen, 2012). Sentiment analysis can thus be regarded as a method to extract knowledge in order to find hidden patterns in an unstructured text or opinion expressed on blogs or tweets. In order to measure a sentiment score, the text’s sentiment is usually compared to a lexicon/dictionary. This comparison determines the strength of the sentiment.

In fact, social network and online digital data created are expected to reach four zettabytes by the end of 2020 (Paper, Ugray & Johnson, 2014). It should be noted also that knowledge discovered through social networks are extremely useful since huge numbers of opinions expressed regarding certain topics are highly unlikely to be biased. This is probably why “social media applications, such as Facebook and Twitter, are increasingly being used by both large and small companies to gain business benefits” (He & Chen, 2014, p. 92). In a similar vein, Parise (2009, p. 2) argues that “social media tools will have a major impact on knowledge management”. However, almost all online communications are noisy and as such pose considerable lexical and syntactic problems (Boiy & Moens, 2009; Derks, Fischer & Bos, 2008; Thelwall, Buckley, Paltoglou, Cai & Kappas, 2010; Pederson, 2001; Dave, Lawrence, & Pennock, 2003; Turney & Littman, 2003). Because of this problem, several online sentiment analyses techniques have been developed in languages as diverse as Arabic (Ahmed & Almas, 2005), Chinese (e.g., Xu, Liao & Li, 2008), English (e.g., Jansen, Zhang, Sobel & Chowdury, 2009), and multi-languages (Abbasi, Chen, & Salem, 2008).

Although several studies have investigated sentiment in different fields (Cai, Spangler, Chen & Zhang, 2010; Leong, Lee & Mak, 2012), no previous studies have focused solely on investigating sentiment of Islamic-related Spanish words of Arabic etymology as used on Twitter. In this study we aim to fill this research gap. We believe that by investigating such words polarity we add depth to the knowledge base on sentiment analysis and text mining. Through the use of both qualitative and quantitative methodologies, we also add breadth to the debate over Islamic-related words sentiment. Finally, by investigating solely Twitter texts, rather than traditional offline data, this research enriches the knowledge base of an under-represented area.

This paper is organized as follows. Next section provides a brief account of related work of major areas of sentiment analysis applications. Section three deals with the research method used to conduct the analysis. In this section issues related to research design, sampling and data analysis techniques are presented. In Section four the results of sentiment analysis are presented. Finally, Section five presents research implications, limitations and explores avenues for future research.

II. LITERATURE REVIEW

Sentiment analysis techniques have been used in diverse areas such as tracking sentiment trends in online discussion boards (e.g., Tong, 2001), differentiating between informative and emotional social media content (Denecke & Nejdi, 2017 ACADEMY PUBLICATION
data representing a random set of Twitter posts from November 15, 2016, to December 15, 2016. The data comprised actually doing. We selected Twitter for this study because it is the most large and popular microblog Web site. We used Twitter users either disseminate information regarding their daily experiences or update their followers on what they Klouman, Harris, Danforth & Dodds, 2012). Thelwall, Buckley and Paltoglou (2011) found that around 80 percent of approximately the size of a newspaper headline. It is estimated that there are around 500 million active twitters (Bliss, Denecke and Deng, 2015).

2012), analyzing drug reviews (Na et al., 2015), supporting decision-making in healthcare (Swain, 2016) such as understanding of attitudes towards immunization (Love et al., 2013), forecasting affordable care markets (Wong, Xia, Xu, Wu & Li, 2008). Tweeting behavior during the Arab Spring was also investigated by several researchers (Papacharissi & Oliveira, 2012; Lim, 2012). Results showed that protesters used Twitter an alternative to the blocked access to the Internet. Park, Lim, Sams, Nam and Park (2011) analyzed Korean politicians’ visitor boards’ comments and found a gender gap in terms of positive and negative comments. Zappavigna (2011) analyzed tweets related to Obama’s presidential elections victory in 2008. Other researchers investigating political sentiment analysis include Efron (2004), Thomas, Pang & Lee (2006) and Park, Kim & Barnett (2004)

Extracting sentiments from consumers’ reviews has been extensively investigated (Blair-Goldensohn, Hannan, McDonald, Neylon, Reis & Reynar, 2008; Yi, Nasukawa, Bunescu & Niblack, 2003). A polarity system to analyze consumers’ comparison comments was developed by Feldman, Fresko, Netzer and Ungar (2007). Hu and Liu (2004) analyzed consumers’ sentiments related to several electronic products such as digital cameras and mobile phones. In a similar vein, Miyoshi and Nakagami (2007) analyzed electronic products consumer sentiments using adjective-noun pairs in a sentence. Zhang, Xu and Wan (2012) analyzed consumers’ sentiments in Chinese language online texts. In fact, this study was an extension of a study reported by Ding, Liu and Yu (2008) and by liu (2010). Pekar & Ou (2008) evaluated 268 reviews of major hotels using attributes such as room service, facilities and food to analyze composite sentiments towards hotels. Na, Khoo and Wu (2005) classified sentiments related to products’ reviews based on data mining techniques.

Na, Thet, and Khoo (2010) analyzed movie reviews by comparing textual characteristics across four different genres. Zhuang, Jing and Zhu (2006) summarized online texts movie reviews sentiments using machine learning techniques. Pang, Lee and Vaithyanathan (2002) classified online sentiments related to movie reviews using support vector machines (SVM). Wijaya & Bressan (2008) used a similar technique, while Na and Khoo (2008a) correctly segmented customers’ reviews into relevant sections pertaining to different aspect of the movie. In another study, the same authors (Thet, Na & Khoo, 2008b) used computational linguistics to segment movie reviews comments.

Das and Chen (2001) analyzed sentiments related to Yahoo! Finance’s discussion board. Gu, Konana, Liu, Rajagopalan and Ghoosh (2006) predicted different stocks’ future returns based on comments posted on the same platform. Bollen, Mao and Zeng (2011) predicted stock market movements using Twitter posts. Other studies investigated investors’ sentiments related to factors such as air disasters (Kaplanski & Levy, 2010), earthquakes (Shan & Gong, 2012), and sports events (Chang, Chen, Chou & Lin, 2012).

Several studies have recently investigated the use of sentiment analysis in patients’ mood detection. For example, Rodrigues et al. (2016) developed a Portuguese language sentiment analysis tool to detect emotional polarity among online cancer community in Brazil. Porter et al. (2013) applied sentiment analysis techniques on online cancer posts in order to detect changes in individuals’ moods as a consequence of interaction with other patients within the same community. In a similar vein, Akay et al. (2015) investigated cancer patients and their families’ sentiments as a reaction to the environment surrounding them. Twitter has been recognized also as a powerful gauge of several medical issues such as understanding of attitudes towards immunization (Love et al., 2013), forecasting affordable care markets (Wong et al., 2015), supporting decision-making in healthcare (Swain, 2016), predicting patients’ feedback (Smith and Lee, 2012), analyzing drug reviews (Na et al. 2012) and investigating medical sentiments concerning patients’ health status (Denecke and Deng, 2015).

III. METHOD

a. Twitter sampling

Launched on July 13, 2006, Twitter revolves around posting short updates of 140 maximum characters, which is approximately the size of a headline. It is estimated that there are around 500 million active twitterers (Bliss, Klouman, Harris, Danforth & Dodds, 2012). Thelwall, Buckley and Paltoglou (2011) found that around 80 percent of Twitter users either disseminate information regarding their daily experiences or update their followers on what they actually doing. We selected Twitter for this study because it is the most large and popular microblog Web site. We used data representing a random set of Twitter posts from November 15, 2016, to December 15, 2016. The data comprised

© 2017 ACADEMY PUBLICATION
4586 out of 45860 tweets generated. All retweets and duplicated tweets were eliminated. Sample selection has been varied by day of the week and hours in the day in order to guarantee representativeness. The sample is comparable in size to similar research studies. For example, Qiu, He, Zhang, Shi, Bu, and Chen (2010) used a sample of 3783 opinion sentences.

b. Lexicon

Miao, Li, and Zeng (2010) argued that there are generally two widely used methods for sentiment orientation. The first one is known in the text mining community as the lexicon-based approach, while the second one is known as the corpus-based method. However, it should be noted that only few authors have used the corpus-based method in analyzing sentiment orientation. Both methods require either a pre-defined dictionary or a corpus of subjective words. In either method, the sentiment score is determined via a comparison between the sentence presented and an expert-defined entry in the dictionary. Several lexicons have been used in the literature such as the General Inquirer (Stone, Dunphy, Smith, & Ogilvie, 1966), the sentiment-based lexicon (Taboada, Brooke, Tofiloski, Voll, & Stede, 2011), the SentiWordNet (Baccianella, Esuli, & Sebastiani, 2010), the LIWC dictionary (Pennebaker, Mehl, & Niederhoffer, 2003), the Q-WordNet (Agerri & Garcia-Serrano, 2010) or the lexicon of subjectivity clues (Wiebe, Wilson, Bruce, Bell, & Martin, 2004). However, in this study we use the Spanish version of the Hu and Liu (2004) lexicon because it has been used successfully in similar applications (Miner, Delen, Elder, Fast, Hill, & Nisbet, 2012). The lexicon is similar in size to the Opinion Finder lexicon (Bollen, Mao, & Zeng, 2011).

IV. RESULTS

Several libraries/software packages such as the twitteR, the maps, the plyr, the stringr and the ggplot2 libraries within the R version 3.3 environment were used to conduct the quantitative sentiment score. Figure 2 shows the distribution of positive sentiment scores obtained, while Figure 3 shows the distribution of negative sentiment scores. From the graphs, we recognize some asymmetry. For example, some words have high bars at the left end (positively skewed), while others show negative skeweness as measured by high tail on the left-hand side of the histogram. The visualization of the sentiment distribution in Figures 2 and 3 further underlines the fact that most words fall on the neutral point (0) or within the band of circa -1/+1. This result is in line with Lindgren (2012), who argued that the focus of sentiment analysis should be on either the positive or negative sentiments.
Figure 3. Major words with negative sentiment scores

Table 1 presents the division of random sample of tweets among each word used in the analysis. Following similar research only Spanish tweets were used to avoid text analysis complications (Thelwall, Buckley & Paltoglou, 2011). From Table 1 we see that most words have a positive sentiment score with the exception of four words (Islam Wahabita, Islamización, Islamismo, and Islamofobia. The overall mean score for the twenty Spanish words of Arabic etymology related to Islamic terminology was 0.2331.

V. IMPLICATIONS, LIMITATIONS AND FUTURE RESEARCH
In this paper we analyzed sentiment polarity of more than 4500 social media tweets expressing sentiments towards twenty Spanish words of Arabic etymology related to Islamic terminology. Although any tweet is limited to 140 characters, millions of tweets posted on Twitter almost on a daily basis. Such tweets might provide an unbiased representation of individuals’ sentiment towards a specific topic. Moreover, such tweets may be used by policy makers to gauge opinions regarding a specific issue. Ignoring such sentiments might put policy makers on the defensive and could also create significant image problems. The speed of social media might also render politicians efforts based on traditional media useless. However, it should be noted that while we conducted sentiment analysis to objectively classify individuals’ opinions towards twenty Spanish words of Arabic etymology related to Islamic terminology, our analysis does not reveal the underlying reasons behind forming such opinions. Thus, future research might use topic recognition techniques in order to determine the most representative topics behind each sentiment, which allows us to gain comprehensive knowledge regarding the underlying causes of positive or negative sentiments. Although the lexicon-based approach we used in this study can detect basic sentiments, it sometimes fails to recognize subtle forms of linguistic expressions (Boiy and Moens, 2009). Finally, individuals’ opinions might in fact be a manipulation of some online opinion makers posing as real individuals. This might distort sentiments of real individuals. Thus, future research should attempt to distinguish genuine sentiments from fake opinions.
